2. Brouwer's Fixed Point Theorem
3. Fixed Points for Correspondences
4. Kakutani's Fixed Point Theorem
5. Separating Hyperplane Theorems

Fixed Points for Functions

Definition 1. *Let* X *be a nonempty set and* $f : X \to X$*. A point* $x^* \in X$ *is a* fixed point *of* f *if* $f(x^*) = x^*$*.*

x^* is a fixed point of f if it is "fixed" by the map f.

x

Fixed Points for Functions

Examples:

1. Let $X = \mathbf{R}$ and $f : \mathbf{R} \to \mathbf{R}$ be given by $f(x) = 2x$. Then $x = 0$ is a fixed point of f (and is the unique fixed point of f).

2. Let $X = \mathbf{R}$ and $f : \mathbf{R} \to \mathbf{R}$ be given by $f(x) = x$. Then every point in $\mathbf{R}$ is a fixed point of f (in particular, fixed points need not be unique).

3. Let $X = \mathbf{R}$ and $f : \mathbf{R} \to \mathbf{R}$ be given by $f(x) = x + 1$. Then f has no fixed points.

4. Let $X = [0, 2]$ and $f : X \to X$ be given by $f(x) = \frac{1}{2}(x+1)$. Then

$$\begin{aligned} f(x) &= \frac{1}{2}(x+1) = x \\ &\iff x + 1 = 2x \\ &\iff x = 1 \end{aligned}$$

So $x = 1$ is the unique fixed point of f. Notice that f is a contraction (why?), so we already knew that f must have a unique fixed point on $\mathbf{R}$ from the Contraction Mapping Theorem.

5. Let $X = [0, \frac{1}{4}] \cup [\frac{3}{4}, 1]$ and $f : X \to X$ be given by $f(x) = 1 - x$. Then f has no fixed points.

6. Let $X = [-2, 2]$ and $f : X \to X$ be given by $f(x) = \frac{1}{2}x^2$. Then f has two fixed points, $x = 0$ and $x = 2$. If instead $X' = (0, 2)$, then $f : X' \to X'$ but f has no fixed points on X'.

7. Let $X = \{1, 2, 3\}$ and $f : X \to X$ be given by $f(1) = 2, f(2) = 3, f(3) = 1$ (so f is a permutation of X). Then f has no fixed points.

8. Let $X = [0, 2]$ and $f : X \to X$ be given by

$$f(x) = \begin{cases} x + 1 & \text{if } x \leq 1 \\ x - 1 & \text{if } x > 1 \end{cases}$$

Then f has no fixed points.

A Simple Fixed Point Theorem

Theorem 1. *Let* $X = [a, b]$ *for* $a, b \in \mathbf{R}$ *with* $a < b$ *and let* $f : X \to X$ *be continuous. Then* f *has a fixed point.*

Proof. Let $g : [a, b] \to \mathbf{R}$ be given by

$$g(x) = f(x) - x$$

If either $f(a) = a$ or $f(b) = b$, we're done. So assume $f(a) > a$ and $f(b) < b$. Then

$$\begin{aligned} g(a) &= f(a) - a > 0 \\ g(b) &= f(b) - b < 0 \end{aligned}$$

g is continuous, so by the Intermediate Value Theorem, $\exists x^* \in (a, b)$ such that $g(x^*) = 0$, that is, such that $f(x^*) = x^*$. □

Brouwer's Fixed Point Theorem

Theorem 2 (Thm. 3.2. Brouwer's Fixed Point Theorem)**.** *Let* $X \subseteq \mathbf{R}^n$ *be nonempty, compact, and convex, and let* $f : X \to X$ *be continuous. Then* f *has a fixed point.*

Sketch of Proof of Brouwer

Consider the case when the set X is the unit ball in $\mathbf{R}^n$, i.e. $X = B_1[0] = B = \{x \in \mathbf{R}^n : \|x\| \leq 1\}$. Let $f : B \to B$ be a continuous function. Recall that ∂B denotes the boundary of B, so $\partial B = \{x \in \mathbf{R}^n : \|x\| = 1\}$.

Fact: Let B be the unit ball in $\mathbf{R}^n$. Then there is no continuous function $h : B \to \partial B$ such that $h(x') = x'$ for every $x' \in \partial B$.

Now to establish Brouwer's theorem, suppose, by way of contradiction, that f has no fixed points in B. Thus for every $x \in B$, $x \neq f(x)$.

Since $x \neq f(x)$ for every x, we can carry out the following construction. For each $x \in B$, construct the line segment originating at $f(x)$ and going through x. Let $g(x)$ denote the intersection of this line segment with ∂B.

This construction is well-defined, and gives a continuous function $g : B \to \partial B$. Furthermore, if $x' \in \partial B$, then $x' = g(x')$. That is, $g|_{\partial B} = \mathrm{id}_{\partial B}$. Since there are no such functions by the fact above, we have a contradiction. Therefore there exists $x^* \in B$ such that $f(x^*) = x^*$, that is, f has a fixed point in B.

Fixed Points for Correspondences

Definition 2. *Let* X *be nonempty and* $\Psi : X \to 2^X$ *be a correspondence. A point* $x^* \in X$ *is a* fixed point *of* Ψ *if* $x^* \in \Psi(x^*)$.

Note here that we do *not* require $\Psi(x^*) = \{x^*\}$, that is Ψ need not be single-valued at x^*. So x^* can be a fixed point of Ψ but there may be other elements of $\Psi(x^*)$ different from x^*.

Examples:

1. Let $X = [0,4]$ and $\Psi : X \to 2^X$ be given by

$$\Psi(x) = \begin{cases} [x+1, x+2] & \text{if } x < 2 \\ [0,4] & \text{if } x = 2 \\ [x-2, x-1] & \text{if } x > 2 \end{cases}$$

   Then $x = 2$ is the unique fixed point of Ψ.

2. Let $X = [0,4]$ and $\Psi : X \to 2^X$ be given by

$$\Psi(x) = \begin{cases} [x+1, x+2] & \text{if } x < 2 \\ [0,1] \cup [3,4] & \text{if } x = 2 \\ [x-2, x-1] & \text{if } x > 2 \end{cases}$$

   Then Ψ has no fixed points.

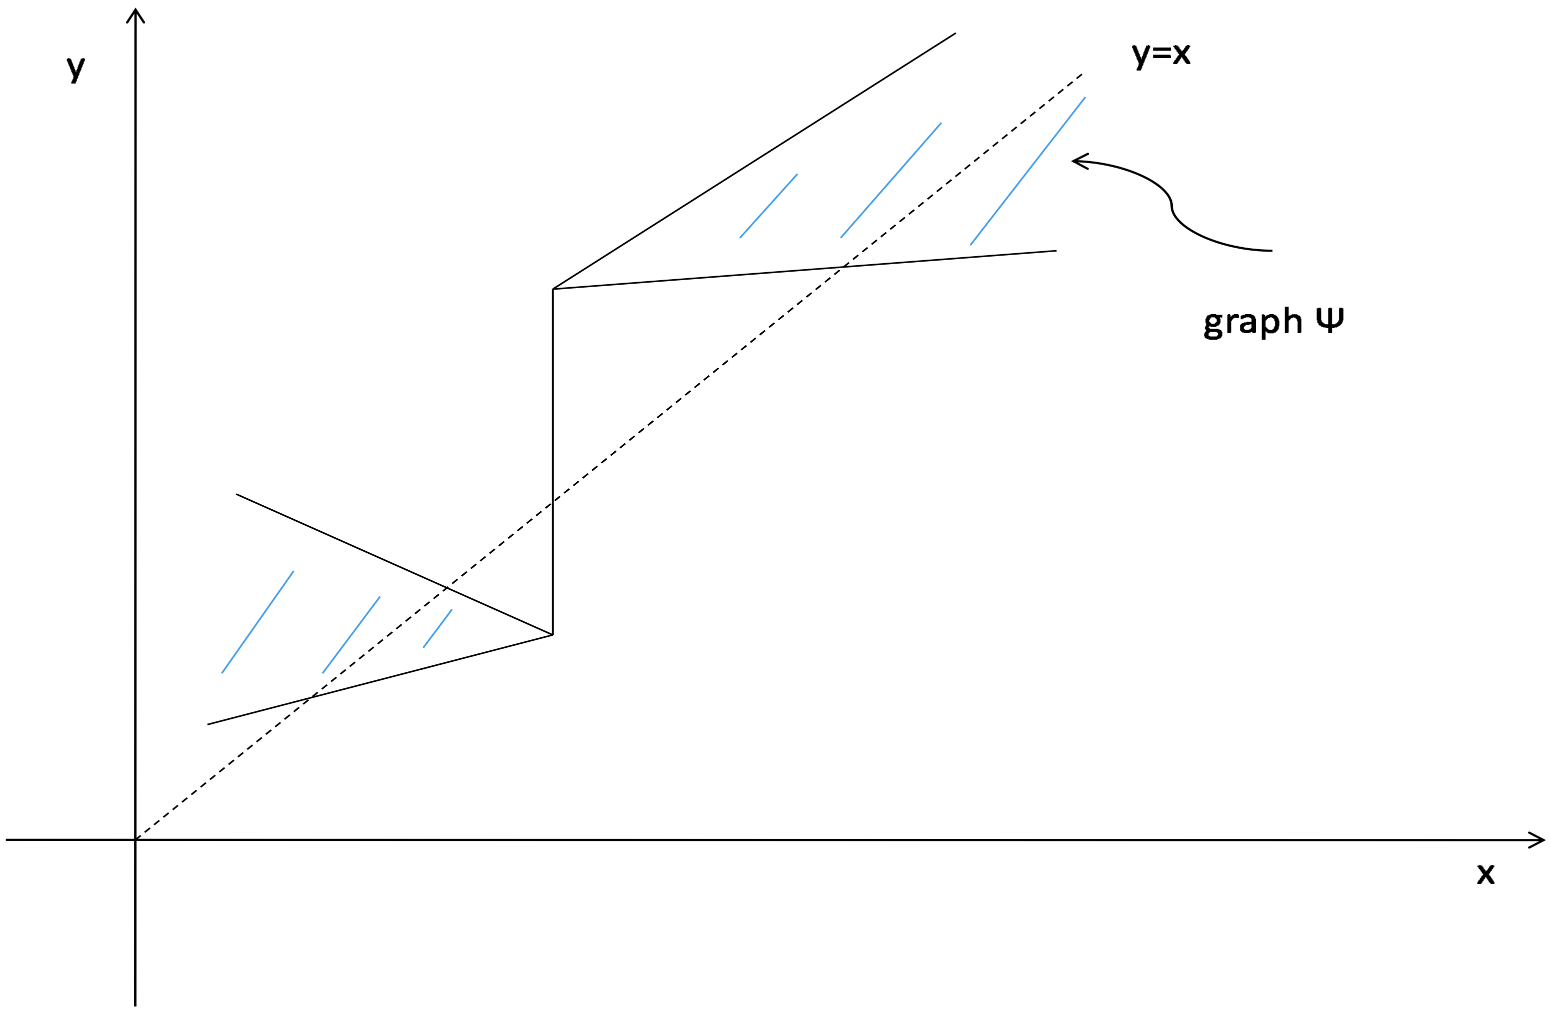
Kakutani's Fixed Point Theorem

Theorem 3. (Thm. 3.4'. Kakutani's Fixed Point Theorem) *Let $X \subseteq \mathbf{R}^n$ be a non-empty, compact, convex set and $\Psi : X \to 2^X$ be an upper hemi-continuous correspondence with non-empty, convex, compact values. Then Ψ has a fixed point in X.*

Proof. **(sketch)** Here, the idea is to use Brouwer's theorem after appropriately approximating the correspondence with a function. The catch is that there won't necessarily exist a continuous selection from Ψ, that is, a continuous function $f : X \to X$ such that $f(x) \in \Psi(x)$ for every $x \in X$. If such a function existed, then by applying Brouwer to f we would have a fixed point of Ψ (because if $\exists x^* \in X$ such that $x^* = f(x^*)$, then $x^* = f(x^*) \in \Psi(x^*)$).

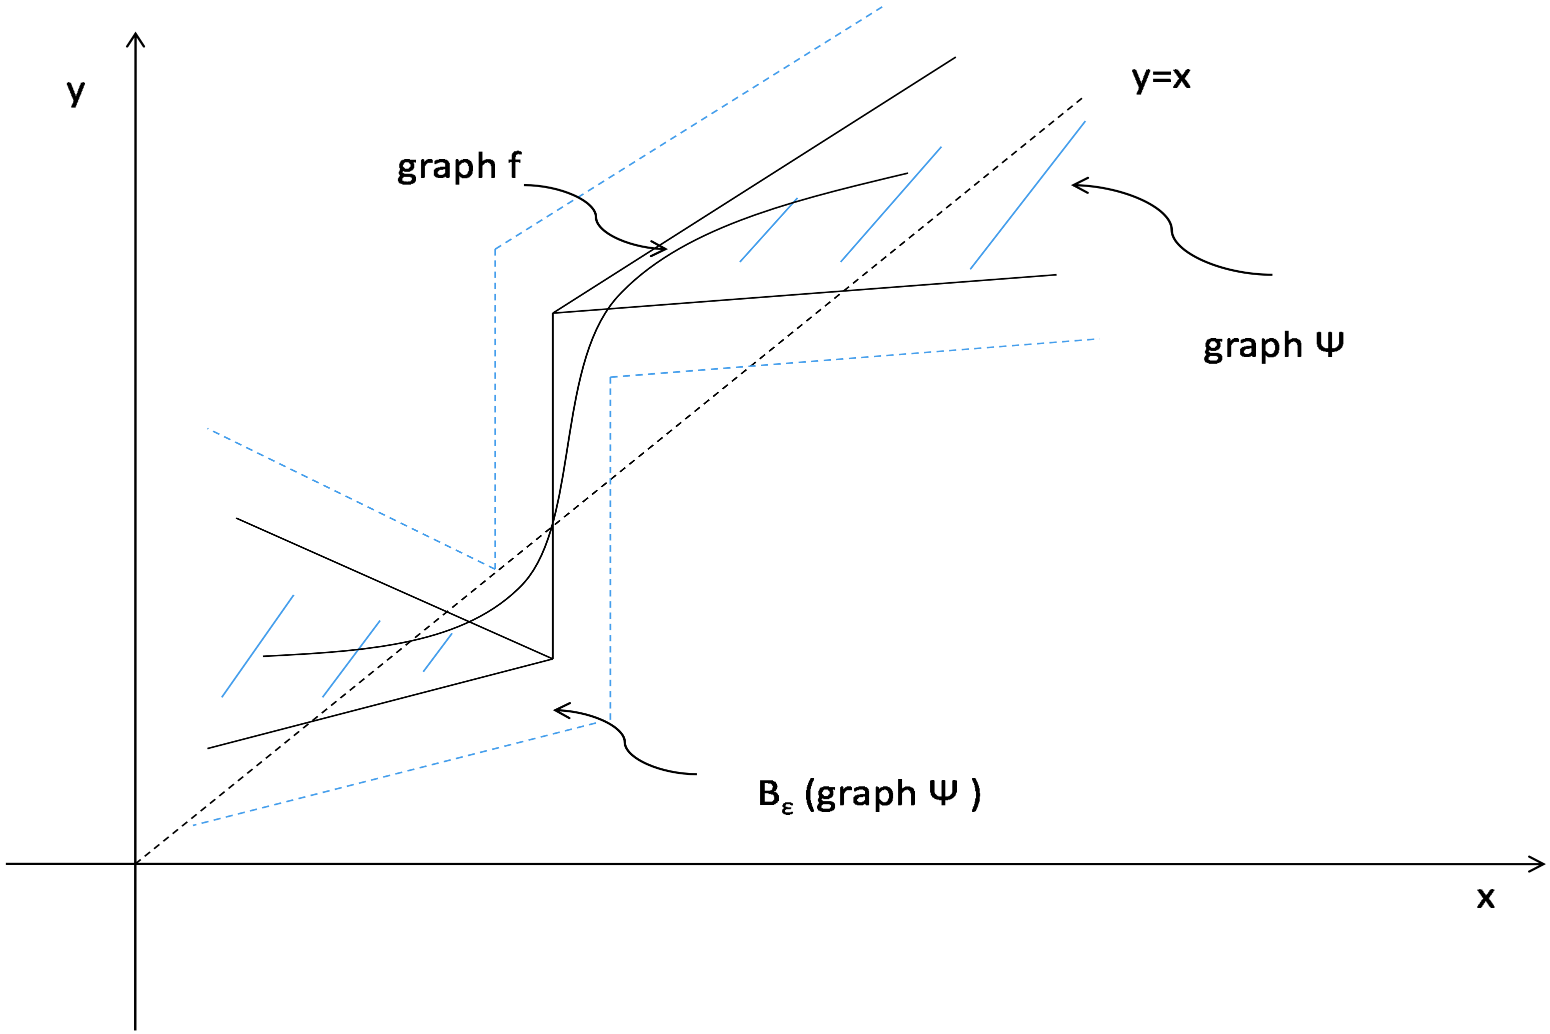


y
y=x
graph Ψ
x

Instead, we look for a weaker type of approximation. Let $X \subset \mathbf{R}^n$ be a non-empty, compact, convex set, and let $\Psi : X \to 2^X$ be an uhc correspondence with non-empty, compact, convex values. For every $\varepsilon > 0$, define the ε ball about graph Ψ to be

$$B_\varepsilon(\text{ graph } \Psi) =$$
$$\left\{ z \in X \times X : d(z, \text{ graph } \Psi) = \inf_{(x,y)\in \text{ graph } \Psi} d(z,(x,y)) < \varepsilon \right\}$$

Here d denotes the ordinary Euclidean distance in $\mathbf{R}^n$. If Ψ is an uhc correspondence, then for every $\varepsilon > 0$ there exists a continuous function $f_\varepsilon : X \to X$ such that graph $f_\varepsilon \subseteq B_\varepsilon($ graph $\Psi)$.



y
y=x
graph f
graph Ψ
B_ε (graph Ψ)
x

Now by letting $\varepsilon \to 0$, this means that we can find a sequence of continuous functions $\{f_n\}$ such that graph $f_n \subseteq B_{\frac{1}{n}}($ graph $\Psi)$ for each n. By Brouwer's Fixed Point Theorem, each function f_n has a fixed point $\widehat{x}_n \in X$, and

$$(\widehat{x}_n, \widehat{x}_n) = (\widehat{x}_n, f_n(\widehat{x}_n)) \in \text{ graph } f_n \subseteq B_{\frac{1}{n}}(\text{ graph } \Psi) \text{ for each } n$$

So for each n there exists $(x_n, y_n) \in$ graph Ψ such that

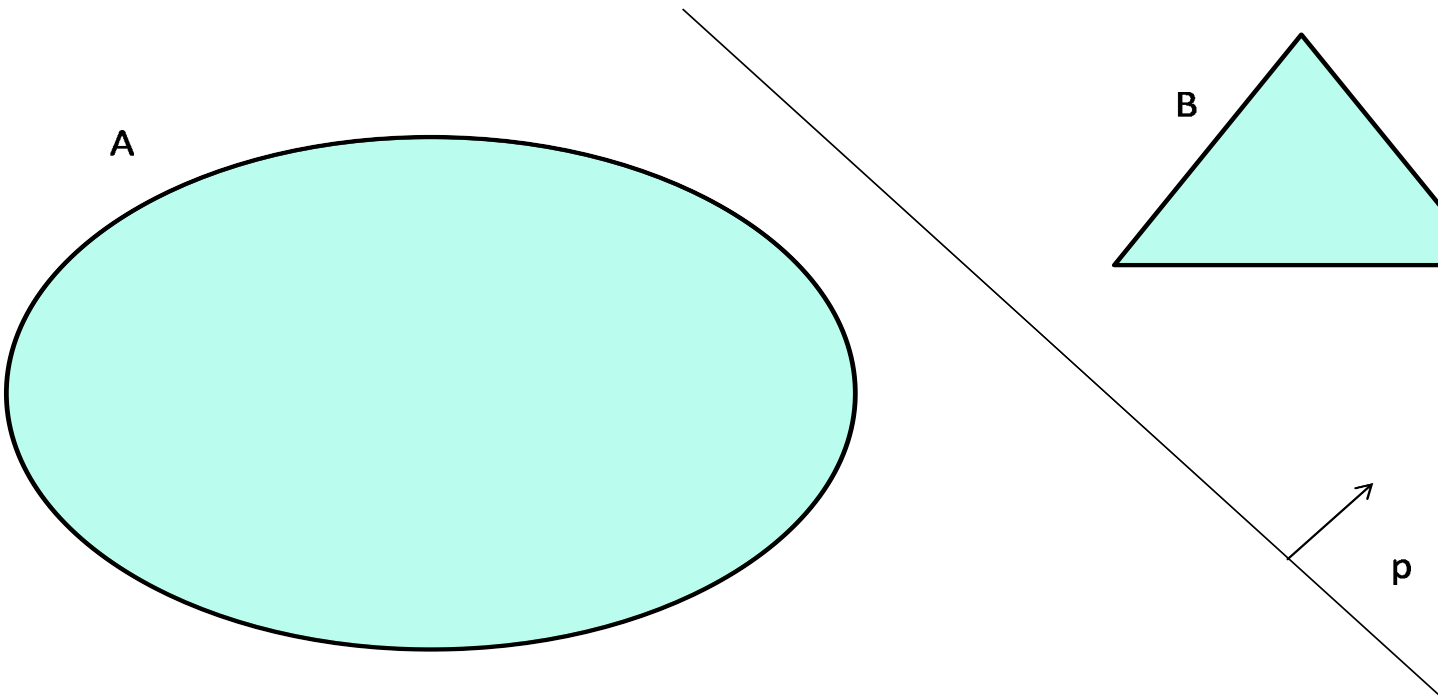
$$d(\widehat{x}_n, x_n) < \frac{1}{n} \text{ and } d(\widehat{x}_n, y_n) < \frac{1}{n}$$

Since X is compact, $\{\widehat{x}_n\}$ has a convergent subsequence $\{\widehat{x}_{n_k}\}$, with $\widehat{x}_{n_k} \to \widehat{x} \in X$. Then $x_{n_k} \to \widehat{x}$ and $y_{n_k} \to \widehat{x}$. Since Ψ is uhc and closed-valued, it has closed graph, so $(\widehat{x}, \widehat{x}) \in$ graph Ψ. Thus $\widehat{x} \in \Psi(\widehat{x})$, that is, $\widehat{x}$ is a fixed point of Ψ. $\square$

Separating Hyperplane Theorems

Theorem 4 (1.26, Separating Hyperplane Theorem)**.** *Let* $A, B \subseteq \mathbf{R}^n$ *be nonempty, disjoint convex sets. Then there exists a nonzero vector* $p \in \mathbf{R}^n$ *such that*

$$p \cdot a \leq p \cdot b \quad \forall a \in A, b \in B$$



A
B

Separating a Point from a Set

Theorem 5. *Let $Y \subseteq \mathbf{R}^n$ be a nonempty convex set and $x \notin Y$. Then there exists a nonzero vector $p \in \mathbf{R}^n$ such that*

$$p \cdot x \leq p \cdot y \quad \forall y \in Y$$

Proof. We sketch the proof in the special case that Y is compact. We will see that in this case we actually get a stronger conclusion:

$$\exists p \in \mathbf{R}^n,\ p \neq 0 \text{ s.t. } p \cdot x < p \cdot y \quad \forall y \in Y$$

Choose $y_0 \in Y$ such that $|y_0 - x| = \inf\{|y - x| : y \in Y\}$; such a point exists because Y is compact, so the distance function $g(y) = |y - x|$ assumes its minimum on Y. Since $x \notin Y$, $x \neq y_0$, so $y_0 - x \neq 0$. Let $p = y_0 - x$. The set

$$H = \{z \in \mathbf{R}^n : p \cdot z = p \cdot y_0\}$$

is the hyperplane perpendicular to p through y_0. See Figure 12. Then

$$\begin{aligned} p \cdot y_0 &= (y_0 - x) \cdot y_0 \\ &= (y_0 - x) \cdot (y_0 - x + x) \\ &= (y_0 - x) \cdot (y_0 - x) + (y_0 - x) \cdot x \\ &= |y_0 - x|^2 + p \cdot x \\ &> p \cdot x \end{aligned}$$

We claim that

$$y \in Y \Rightarrow p \cdot y \geq p \cdot y_0$$

If not, suppose there exists $y \in Y$ such that $p \cdot y < p \cdot y_0$. Given $\alpha \in (0, 1)$, let

$$w_\alpha = \alpha y + (1 - \alpha) y_0$$

Since Y is convex, $w_\alpha \in Y$. Then for α sufficiently close to zero,

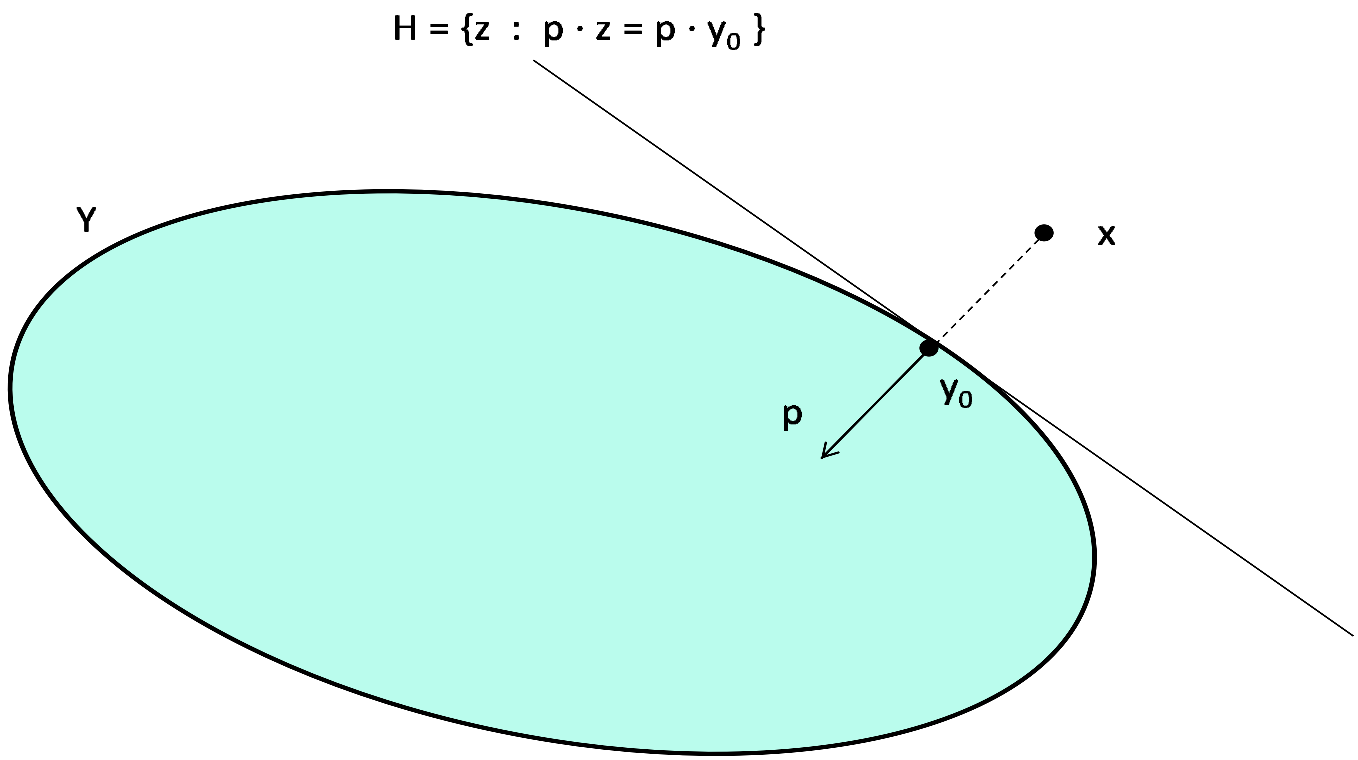
$$\begin{aligned}
|x - w_\alpha|^2 &= |x - \alpha y - (1-\alpha)y_0|^2 \\
&= |x - y_0 + \alpha(y_0 - y)|^2 \\
&= |-p + \alpha(y_0 - y)|^2 \\
&= |p|^2 - 2\alpha p \cdot (y_0 - y) + \alpha^2 |y_0 - y|^2 \\
&= |p|^2 + \alpha\left(-2p \cdot (y_0 - y) + \alpha |y_0 - y|^2\right) \\
&< |p|^2 \quad \text{for } \alpha \text{ close to } 0, \text{ as } p \cdot y_0 > p \cdot y \\
&= |y_0 - x|^2
\end{aligned}$$

Thus for α sufficiently close to zero,

$$|w_\alpha - x| < |y_0 - x|$$

which implies y_0 is not the closest point in Y to x, contradiction.

□



$H = \{z : p \cdot z = p \cdot y_0\}$
Y
x
p
y_0

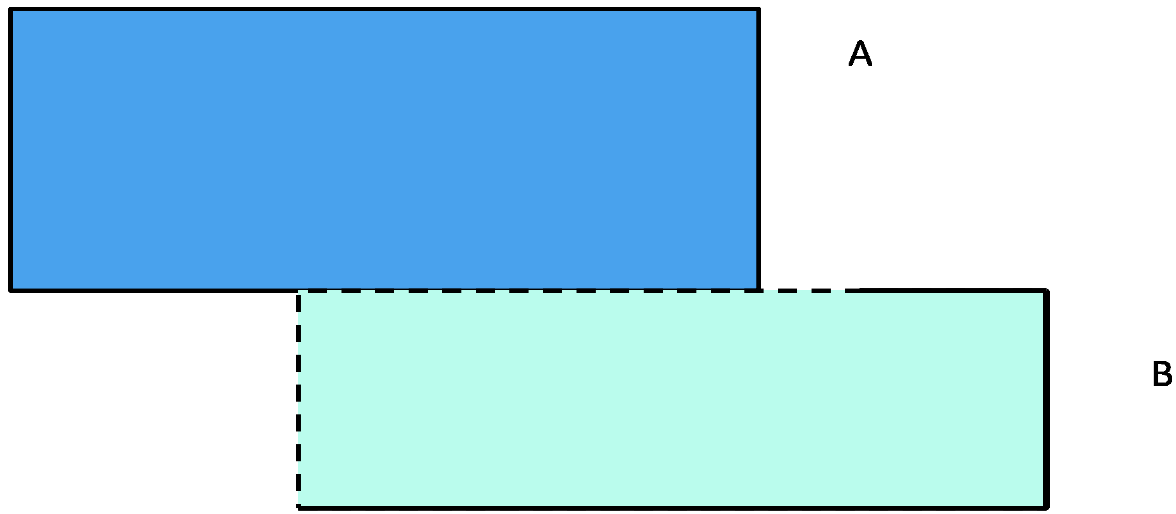
The general version of the Separating Hyperplane Theorem can be derived from this special case by noting that if $A \cap B = \emptyset$, then $0 \notin A - B = \{a - b : a \in A, b \in B\}$.

Strict Separation

For the special case of Y compact and $X = \{x\}$, we actually could *strictly separate* Y and X:

$$\exists p \in \mathbf{R}^n,\, p \neq 0 \text{ s.t. } p \cdot x < p \cdot y \quad \forall y \in Y$$

When can we do this in general? Will require additional assumptions...



A
B

Strict Separation

Theorem 6. (Strict Separating Hyperplane Theorem) *Let* $A, B \subseteq \mathbf{R}^n$ *be nonempty, disjoint, closed, convex sets. Then there exists a nonzero vector* $p \in \mathbf{R}^n$ *such that*

$$p \cdot a < p \cdot b \quad \forall a \in A, b \in B$$
