2.2. The role of aggregate demand shocks

A second model, based on closed-economy models by Barro and Gordon (1983) and Kydland and Prescott (1977), shows that a regime of fixed but adjustable parities can engender multiple equilibria. In some equilibria the economy may be worse off than under irrevocably fixed exchange rates, as nominal wage-growth expectations erode competitiveness and make devaluations more frequent⁽²⁾. In this model devaluations are triggered by the government's desire to offset negative output shocks, but a sudden shift in market sentiment regarding the government's willingness to tolerate unemployment can trigger a devaluation that would not have occurred under different private expectations.

In this model, lower case variables denote natural logarithms and PPP holds, so that e , the (log) home-currency price of foreign exchange, equals p , the (log) money price of domestic output, given
