## **Abstract**

A negative aggregate demand shock driven by household deleveraging is responsible for a large fraction of the decline in U.S. employment from 2007 to 2009. The deleveraging – aggregate demand hypothesis predicts that employment losses in the *non-tradable* sector will be higher in high leverage U.S. counties that experienced the bulk of the deleveraging process, while losses in the *tradable* sector will be distributed uniformly across all counties. We find exactly this pattern from 2007 to 2009. Alternative hypotheses for job losses based on uncertainty shocks or structural unemployment related to construction do not explain our results. Using the relation between non-tradable sector job losses and household leverage and assuming Cobb-Douglas preferences over tradable and non-tradable goods, we quantify the effect of deleveraging on total employment. Our estimates suggest that the decline in aggregate demand driven by deleveraging accounts for 4 million of the lost jobs from 2007 to 2009, or 65% of the lost jobs in our data.

\*We thank seminar participants at New York University (Stern) and Columbia Business School for comments. Lucy Hu, Ernest Liu, and Calvin Zhang provided superb research assistance. We are grateful to the National Science Foundation, the Initiative on Global Markets at the University of Chicago Booth School of Business and the Center for Research in Security Prices for funding. The results or views expressed in this study are those of the authors and do not reflect those of the providers of the data used in this analysis. A sustained high level of unemployment is one of the biggest and most vexing problems in macroeconomics. The issue is especially relevant today: the employment to population ratio dropped from 63% in 2007 to 58% in 2009 where it remains as of the summer of 2011. The problem has been difficult to address in part because there is a lack of consensus on the reasons for unemployment. There are many hypotheses put forth to explain job losses including a decline in aggregate demand, business uncertainty, and structural adjustment of the labor force.

Our analysis is motivated by recent research showing that deleveraging of the household sector is a primary reason for the both the depth of the recession and length of the economic slump (e.g., Mian and Sufi (2010), Mian, Rao, and Sufi (2011), Eggertsson and Krugman (2011), Guerrieri and Lorenzoni (2011), Hall (2011), Midrigan and Philippon (2011)). In particular, Mian and Sufi (2010) and Mian, Rao, and Sufi (2011) exploit geographical variation across U.S. counties in the degree of household leverage as of 2006, and demonstrate that deleveraging is responsible for a large fraction of the decline in consumption from 2006 to 2010.

Can deleveraging and the associated decline in consumer demand in high leverage counties explain the sharp reduction in employment in the U.S. from 2007 to 2009? We show that the answer to this question is a resounding yes. We refer to this channel as the *deleveraging – aggregate demand hypothesis*, and our analysis demonstrates that it explains a substantial fraction of jobs lost during this time period.

Our test of this hypothesis is based on one of its main implications: a negative consumer demand shock in a given location should reduce employment in industries producing non-tradable goods in that specific location, but should reduce employment in industries producing tradable goods throughout the country. For example, when Californians cut back on consumption significantly more than Texans, the non-tradable sector in California loses more jobs than the

non-tradable sector in Texas. However, because Californians buy tradable goods produced throughout the country, job losses in the tradable sector will be distributed evenly across all counties, including those in Texas.

Our empirical approach tests this basic prediction of the deleveraging-aggregate demand hypothesis by utilizing *industry-by-county* data on employment patterns during the economic slump. We split consumption goods into those consumed locally (*non-tradable*) and those consumed nationally (*tradable*). Industries are classified as non-tradable if they are focused in the retail or restaurant business. In order to remove any direct effect of the residential housing boom and bust, we explicitly remove construction or any other real-estate related sector from the non-tradable definition.

Consistent with the deleveraging-aggregate demand hypothesis, job losses in the non-tradable sector from 2007 to 2009 are significantly higher in high leverage counties. In particular, a one standard deviation increase in the 2006 debt to income ratio of a county is associated with a 3 percentage point drop in non-tradable employment during this time period, which is  $2/5$  a standard deviation. Moreover, the large decline in employment in the tradable sector is completely uncorrelated with 2006 debt to income – exactly as predicted by the deleveraging-aggregate demand hypothesis.

Can the cross-sectional job loss patterns in non-tradable and tradable sectors be explained by alternative hypotheses? One explanation for sustained low employment levels is based on heightened economic and policy uncertainty. However, in its most basic form, the uncertainty view does not predict such large cross-sectional differences across the country in employment losses. Further, it is unlikely that the uncertainty hypothesis can rationalize the distinct relations between household leverage and non-tradable versus tradable sector job losses that we find here.

A second explanation for unemployment is based on the structural adjustment of the labor force, as displaced labor from overly-inflated housing, construction, and financial sectors relocate to alternative sectors. One may also argue that such structural adjustment issues are more prevalent in more levered counties. However, we show that this argument is unlikely to be an explanation for our results for several reasons. First, our definition of non-tradable job losses explicitly removes job losses associated with construction and other related industries. Second, including control variables for either the construction share of employment as of 2007 or the growth in the construction sector from 2000 to 2007 does not change our results. In fact, these controls are uncorrelated with non-construction non-tradable sector job losses.

Further, we show that both the construction share as of 2007 and the growth in the construction sector during the housing boom are uncorrelated with county-level household leverage when instrumented with housing supply elasticity. The reason for this perhaps surprising result is that low housing supply elasticity areas had higher price appreciation during the boom and hence more leverage, but it was also more costly to expand the housing stock in these areas.<sup>1</sup>

We also examine other margins of adjustment in the labor market. Given the disproportionate job losses in high leverage counties, one would expect to find evidence of a relative wage decline in these counties. We find such evidence: a one standard deviation increase in household leverage is associated with a 1/5 standard deviation reduction in wages. One might also expect that workers would move out of high household leverage counties in response to deterioration in local labor markets. However, we find no evidence of such mobility. In fact, as

---

<sup>1</sup> As an additional point, it is difficult for the structural adjustment argument to quantitatively explain the increase in aggregate employment since the bulk of the employment losses occurred in non-construction tradable industries.

of 2009, net migration into high leverage counties is positive. Mobility out of high household leverage counties does not explain the employment losses in these areas.

In the final section of our analysis, we use our results to quantify the *total* employment losses due to the deleveraging-aggregate demand channel. Our methodology for doing so is based on the insight that one can use the cross-sectional county level estimate of the effect of deleveraging on unemployment in the *non-tradable* sector to back out the effect of deleveraging on unemployment in *all* sectors.<sup>2</sup> We estimate that deleveraging of the household sector can account for 4 million of the 6.2 million jobs lost between March 2007 and March 2009. The methodology behind this calculation is described in Section 2 and the details of this aggregate calculation are in Section 5. Taken together, our results suggest that a decline in aggregate demand driven by household deleveraging is the primary explanation for high and persistent unemployment during the economic slump.

Our empirical analysis is most closely related to Mian and Sufi (2010) and Midrigan and Philippon (2011). Mian and Sufi (2010) show a negative correlation between employment growth during the recession and county-level leverage ratios, but note that a disadvantage of their analysis is the inability to separate local employment losses due to local versus national demand shocks. Our empirical methodology is designed to overcome this exact problem.

Midrigan and Philippon (2011) build a general equilibrium model in which the recession is triggered by differential shocks across states in the ability to use housing to finance immediate consumption. In estimating parameters for their model, they utilize state level correlations between ex ante leverage ratios and construction employment, consumption, and deleveraging.

---

<sup>2</sup> This methodology requires assumptions such as Cobb-Douglas preferences over tradable and non-tradable goods and an elasticity of labor demand with respect to product demand that is constant across sectors. We address these assumptions in detail in Section 2.

Our approach here is complementary. We use micro data on employment in tradable and non-tradable industries to estimate the aggregate effect of deleveraging on unemployment.

The rest of the study proceeds as follows. In the next section we provide motivation for the methodology which we outline in Section 2. Section 3 presents the data and our classification scheme for tradable and non-tradable goods. Section 4 presents the results of our analysis. Section 5 conducts our final aggregate calculation and Section 6 concludes.

### **Section 1: Motivation and Background**

The U.S. economy experienced a tremendous increase in household debt in the years preceding the economic downturn. Household debt doubled from \$7 trillion to \$14 trillion from 2001 to 2007, and the debt to GDP ratio skyrocketed from 0.7 to 1.0 over the same time period. The increase in debt was closely related to the rise in house prices. For example, Mian and Sufi (2011) show that, holding income constant, homeowners borrowed aggressively against the increase in house prices during this time period.

Theoretical research argues that the elevated level of household debt has been critical in explaining the onset, depth, and length of the current economic slump. Models by Eggertsson and Krugman (2011), Guerrieri and Lorenzoni (2011), Hall (2011), and Midrigan and Philippon (2011) explain the onset and depth of the recession using a combination of tightened credit constraints related to the collapse in house prices in combination with nominal rigidities including the zero lower bound on nominal interest rates. While the models are distinct in the precise nature of the deleveraging shock, all imply that a decline in aggregate demand driven by

an over-levered household sector responding to tightened credit limits is a key driving force explaining the recession.<sup>3</sup>

Empirical evidence in Mian and Sufi (2010) and Mian, Rao, and Sufi (2011) support these models. In particular, Mian and Sufi (2010) and Mian, Rao, and Sufi (2011) exploit geographic variation across U.S. counties in the degree of leverage as of 2006. The geographic variation proxies well for the borrower heterogeneity that is present in the theoretical models described above. Consistent with the deleveraging intuition, these studies show that highly levered U.S. counties were the driving force behind sharp drops in consumption during the downturn.

Figure 1 summarizes these findings. To construct the figure, we split U.S. counties into four quartiles based on the debt to income ratio as of 2006.<sup>4</sup> High (low) household leverage counties are counties in the top (bottom) quartile of the 2006 debt to income distribution. In order to ensure an easy assessment of magnitudes, we weight counties by the outcome variable in question; in other words, both high and low leverage counties contain the same amount of the outcome variable in question as of 2006.<sup>5</sup>

The top left panel shows that high household leverage counties experienced much more severe house price declines during the recession and afterward. House prices declined from 2006 to 2010 by almost 30% in these areas. The decline was 40% if we were to show the Fiserv Case Shiller Weiss index instead of FHFA. The decline in house prices represented a severe credit shock to households. As the top left panel shows, home equity limits from 2007 to 2010 declined

---

<sup>3</sup> Eggertsson and Krugman (2011) and Hall (2011) argue that the zero lower bound on nominal interest rates is the main nominal rigidity that makes the deleveraging-driven decline in aggregate demand crucial for understanding the economic slump. It is not obvious theoretically that unemployment should result. See Hall (2011) in particular for a discussion of this point.

<sup>4</sup> Debt is measured from Equifax and income from the IRS. See Section 3 for more details.

<sup>5</sup> See Mian and Sufi (2010) and Mian, Rao, and Sufi (2011) for more detail on the construction of and data in these figures. For house prices, we weight by total population when constructing the quartiles.

by 25% in high leverage counties. The shock to credit availability translated into lower household borrowing. From 2007 to 2010, debt in these counties dropped by 15%, which translates into \$600 billion. And the real effects are clear: high household leverage counties experienced a drop in auto sales of 50% from 2006 to 2009, with only a slight recovery in 2010.

The magnitude of the drops in these variables is much smaller in counties with low household leverage before the recession. As of 2010, house prices were still up relative to 2006, home equity limits had dropped only 8%, and household borrowing was down only slightly relative to the 2008 peak. Auto sales dropped even in low leverage counties, but the drop was much less severe and the recovery in 2010 was stronger. Mian, Rao, and Sufi (2011) show that the pattern in auto sales in Figure 1 also holds for consumption across other goods, including furniture, appliance, and grocery spending. For example, in low leverage counties, furniture spending from 2006 to 2010 declined by 40% less and grocery spending increased by 23% more than in high leverage counties.

There is no doubt that the decline in consumption levels from 2007 to 2010 was much more severe in counties with elevated levels of household debt at the beginning of the recession. This is consistent with the deleveraging-aggregate demand based models described above. The key question of our analysis is the following: how much of the decline in employment is directly related to the deleveraging-driven aggregate demand shock?

Figure 2 presents a first attempt to answer this question. It plots employment growth from 2007 to 2009 against the 2006 debt to income ratio for U.S. counties.<sup>6</sup> There is a strong negative correlation--counties with high household leverage before the recession experienced much sharper declines in employment during the recession. Column 1 of Table 1 presents the weighted

---

<sup>6</sup> Employment at the county level is measured using the Census County Business Patterns data. These data are measured in mid-March of each year. See Section 3 for more details. The figure includes the top 450 counties that have at least 50,000 households.

least squares version of the scatter-plot in Figure 1. The coefficient in column 1 implies that a one standard deviation increase in the 2006 debt to income ratio is associated with a 1.7 percentage decline in employment from 2007 to 2009, which is 1/3 standard deviation.<sup>7</sup> The specification reported in column 2 restricts the sample to counties in Figure 2, i.e. counties with more than 50,000 households as of 2000, and shows a similar estimate.

In evaluating these estimates, an important issue is the source of variation in 2006 county-level leverage ratios. This issue is discussed at length in Mian and Sufi (2009), Mian and Sufi (2011), and Mian, Rao, and Sufi (2011). Mian and Sufi (2009) provide evidence of a sharp increase in the *supply* of mortgage credit in the U.S. from 2002 to 2006. They also show that the house price impact of the increased supply of mortgage credit was not uniform across the country: areas that were more constrained in their capacity to supply housing (e.g., due to difficult-to-build terrain as identified by Saiz (2011)) experienced larger house price gains as credit supply expanded.

Mian and Sufi (2011) use individual level panel data on consumer borrowing to show that U.S. households borrowed 25 to 30 cents for every dollar increase in the value of their housing. This home-equity based borrowing represents a large fraction of the overall increase in U.S. household leverage between 2002 and 2006. In short, the increase in supply of credit to the U.S. led to sharper rise in house prices in counties that had more difficult-to-build terrain. The increase in house prices in turn allowed home owners living in these counties to increase their leverage to unprecedented levels. While this mechanism does not explain all of the cross-sectional variation in leverage by 2006, it does explain a major portion of it.<sup>8</sup>

---

<sup>7</sup> All standard deviation comparisons use the sample standard deviation where observations are weighted by the total number of households as of 2000.

<sup>8</sup> In particular, cities in Arizona and Nevada are important outliers. See Mian and Sufi (2009, 2011) for more details.

Taken together, these results suggest that a natural instrument for the 2006 leverage ratio is the elasticity of housing supply in the county (Saiz (2011)).<sup>9</sup> The Saiz elasticity measure is available for 877 counties. Column 3 repeats the column 1 regression for this sub-sample and gets similar results. Column 4 presents the first stage regression of debt to income on housing supply elasticity which indeed predicts leverage strongly. A one standard deviation increase in elasticity leads to a 1/2 standard deviation lower 2006 debt to income ratio in the county. The instrumental variables estimate of leverage on employment is in column 5 and is similar to its WLS counterpart in column 3.

As we discuss further in Section 3, the instrumental variables estimate is valuable given that the predicted value of the 2006 county level debt to income ratios is uncorrelated with other confounding variables. In particular, once instrumented, 2006 county level leverage ratios are *uncorrelated* with both the share of construction workers in 2007 and the growth in the construction industry during the housing boom. This will allow us to cleanly separate the deleveraging hypothesis from the construction-related structural adjustment hypothesis.

## **Section 2: Empirical Framework**

The evidence in Figure 2 and Table 1 is useful as motivation, but has an obvious drawback. Even if the entire decline in consumption during the recession was concentrated in high leverage counties, we would not expect employment losses to be entirely concentrated in the same counties. The reason is obvious: goods consumed in high leverage counties are not necessarily produced in the same county. As a result, the correlation between total employment growth and the deleveraging shock at the county level *under-estimates* the true impact of

---

<sup>9</sup> The Saiz (2011) measure is constructed at the CBSA level. For the 877 counties for which the Saiz (2011) data are available, there are 260 CBSAs. The average number of counties per CBSA is 3 and the median is 2.

deleveraging on employment. In this section, we outline the empirical strategy for overcoming this problem.

### A. Basic framework

Consider an economy made up of  $N$  equally sized counties or “islands” indexed by  $c$ . Each county produces two types of goods, tradable ( $T$ ) and non-tradable ( $NT$ ). Counties can freely trade the tradable good among themselves, but must consume the non-tradable good produced in their own county. Consumers have Cobb Douglas preferences with weights  $\alpha$  and  $(1 - \alpha)$  given to the non-tradable and tradable good, respectively. Cobb Douglas preferences imply that in response to a deleveraging shock, consumers cut back on the two types of goods proportionately.<sup>10</sup>

Counties differ in the extent of the deleveraging-induced demand shock, which we denote by  $\delta_c$ . Without loss of generality we index counties such that  $\delta_{c+1} > \delta_c$ , so county 1 is hit with the smallest deleveraging shock and county  $N$  with the strongest. Moreover  $\delta_c$  is measured in units of the consumption decline in county  $c$ .

Households in a county consume goods produced in their own county and other counties. As a result, we need to separate the household demand shock  $\delta_c$  in a county from the decline in demand faced by *producers* in county  $c$ . Let  $\gamma_c$  represent the decline in demand faced by all producers in county  $c$ . Then given Cobb Douglas preferences and the distribution of  $\delta_c$ :

$$\gamma_c = \alpha\delta_c + (1 - \alpha)\bar{\delta} \tag{1}$$

Where  $\bar{\delta} = \frac{1}{N} \sum_{c=1}^N \delta_c$ . Let  $\beta$  represent the elasticity of employment with respect to output demand. Then the employment decline in county  $c$  is given by  $\beta\gamma_c$ . As equation (1) makes clear,

---

<sup>10</sup> Both Eggertsson and Krugman (2011) and Guerrieri and Lorenzoni (2011) model the deleveraging shock as a tightening of the borrowing constraint on levered households. Levered households respond to the shock by reducing consumption substantially.

the employment decline in a county depends on both the *local demand shock for non-tradable goods*  $\alpha\delta_c$  as well as the *county's production share of the aggregate demand shock for tradable goods*  $(1 - \alpha)\bar{\delta}$ .

### B. Other sources of employment loss

We have so far assumed that deleveraging is the only source of employment losses in the economy. However, there may be alternative reasons for employment declines that we must consider when taking the deleveraging hypothesis to the data. We consider two other mechanisms highlighted in the literature. First, declines in output and employment may be due to economy-wide factors such as uncertainty shocks (Bloom (2009)). Second, certain counties may be more exposed to employment losses due to “structural unemployment.” For example, if the economic decline is driven by a re-allocation of resources away from finance and construction toward other sectors, then counties with larger gains from finance and construction in the housing boom period will have more unemployed workers. Unemployment may remain high as these unemployed workers are retrained for new jobs.

Let  $\eta$  denote employment losses common to all counties due to economy wide factors such as uncertainty shocks and let  $s_c$  denote employment losses in county  $c$  due to structural shocks. Then total employment losses  $Y_c$  in a county are given by:

$$Y_c = \beta\alpha\delta_c + \beta(1 - \alpha)\bar{\delta} + \eta + s_c \quad (2)$$

### C. Isolating the impact of the deleveraging shock on aggregate employment

Equation (2) represents total employment losses in a given county inclusive of the three main hypotheses we have considered. The *aggregate* employment losses from deleveraging shocks  $\delta_c$  are obtained by first summing the county-level employment shocks that come from the decline in *local demand for non-tradable goods* and then adding employment losses from the

decline in the *aggregate demand for tradable goods*. Doing so gives us an aggregate non-tradable goods demand effect of  $N\beta\alpha\bar{\delta}$  and the total aggregate tradable goods demand effect of  $N\beta(1 - \alpha)\bar{\delta}$ .<sup>11</sup> Therefore, the total employment loss due to deleveraging is  $JOBSLOSTDELEVER = N\beta\bar{\delta}$  and depends only on the aggregate shock  $\bar{\delta}$ .

We next illustrate how  $JOBSLOSTDELEVER$  can be estimated using county-level data. The estimation of  $JOBSLOSTDELEVER$  requires two additional steps: we must remove the effects of structural unemployment  $s_c$  and the economy wide shock  $\eta$  from (2), and we need a suitable measure of  $\delta_c$ .

We define the non-tradable sector as the sector that is non-tradable *and* not exposed to structural unemployment.<sup>12</sup> Then employment losses in the non-tradable sector can be written as:

$$Y_c^{NT} = \beta\alpha\delta_c + \alpha\eta \quad (3)$$

where  $Y_c^{NT}$  represents employment losses in the non-tradable sector, where  $Y_c = Y_c^{NT} + Y_c^T$  and  $Y_c^T = \beta(1 - \alpha)\bar{\delta} + (1 - \alpha)\eta + s_c$ . Equation (3) takes out the impact of structural employment by limiting itself to the non-tradable sector.

A problem with the estimation of equation (3) is that the actual county-level deleveraging shock  $\delta_c$  is not directly observed. However, suppose that there is an observable county characteristic  $X_c$  such that  $X_c$  is monotonically related to  $\delta_c$  (and hence  $\alpha\delta_c$ ). In our context,  $X_c$  represents the debt to income ratio as of 2006 which we have already shown in Figure 1 is strongly correlated with both deleveraging and strength of the consumer demand decline across counties (see also Mian and Sufi (2010) and Mian, Rao, and Sufi (2011)).

---

<sup>11</sup> That is:  $\sum_{c=1}^N \beta\alpha\delta_c + \sum_{c=1}^N \beta(1 - \alpha)\bar{\delta}$

<sup>12</sup> In the empirical section, this translates into removing construction and real-estate related industries from the definition of non-tradable goods.

We can use  $X_c$  to back out the marginal effect of the deleveraging demand shock  $\delta_c$  on non-tradable employment. To see this, rewrite (3) in differences such that,

$$\Delta Y_c^{NT} = Y_c^{NT} - Y_1^{NT} = \beta(\alpha\delta_c - \alpha\delta_1) \quad (4)$$

The differencing in equation (4) has stripped out the effect of economy wide shock  $\eta$  from the equation. More importantly, given the monotonic relationship between  $X_c$  and  $\delta_c$ , an unbiased estimate of  $\Delta Y_c^{NT}$  is given by:

$$[E(Y_c^{NT}|X_c) - E(Y_1^{NT}|X_1)] \quad (5)$$

The term in square brackets can be estimated non-parametrically, or if the relationship between  $Y_c^{NT}$  and  $X_c$  is linear then via standard OLS. Let  $\widehat{\Delta Y_c^{NT}} = [E(Y_c^{NT}|X_c) - E(Y_1^{NT}|X_1)]$ , be an unbiased estimate for  $\Delta Y_c^{NT}$  then

$$\sum_{c=2}^N \widehat{\Delta Y_c^{NT}} = \sum_{c=2}^N \beta(\alpha\delta_c - \alpha\delta_1) = \alpha N\beta\bar{\delta} - \alpha N\beta\delta_1 \quad (6)$$

Equation (6) and the analysis above gives us the following proposition that summarizes our methodology for estimating *JOBSLOSTDELEVER*.

*Proposition 1:* As long as the employment effect of the deleveraging shock is non-positive for the county that is least impacted by deleveraging (i.e.  $\alpha\beta\delta_1 \geq 0$ ), the estimate  $\frac{1}{\alpha} [\sum_{c=2}^N \widehat{\Delta Y_c^{NT}}]$  represents an underestimate of the total employment loss in the economy due to the deleveraging-driven aggregate demand shock.

The parameter  $\alpha$  can be estimated as the share of non-tradables in the overall economy. In our empirical analysis that follows, we will explicitly test for the condition  $\alpha\beta\delta_1 \geq 0$  and implement the methodology summarized in Proposition 1.

#### *D. Other possible general equilibrium effects*

Our primary focus is on estimating the employment consequences of deleveraging shocks  $\delta_c$ . However as Midrigan and Philippon (2011) show, heterogeneous deleveraging shocks faced by different counties can also potentially impact relative wages across counties and labor

mobility. For example, relative wages could decline in areas harder hit by the deleveraging shock. The relative drop in wages could in turn make these counties more competitive in the tradable sector production. The net impact of these labor market adjustments depends on parameters such as wage and labor market rigidity. In the empirical section that follows, we explicitly consider these general equilibrium effects as well.

### **Section 3: Data, Industry Classification, and Summary Statistics**

#### *A. Data*

County by industry employment and payroll data are from the County Business Patterns (CBP) data set published by the U.S. Census Bureau. CBP data are recorded in March each year. The most recent data available is for 2009. We use CBP data at the 4-digit industry level, so we know the breakdown of number of employees and total payroll bill within a county for every 4-digit industry. We place each of the 4-digit industries into one of four categories: non-tradable, tradable, construction and other. We discuss the classification scheme in the next subsection. We supplement the CBP data with hourly wage data from the annual American Community Survey (ACS). ACS is based on a survey of 3 million U.S. residents conducted annually.

As mentioned above, a key variable in the analysis is the leverage ratio of a county, which is measured as the debt to income ratio as of 2006. Total debt in a county is measured using consumer credit bureau data from Equifax and income is measured as total wages and salary in a county according to the Statistics of Income by the IRS. For more information on these data sources, see Mian and Sufi (2010).

#### *B. Classifying industries into tradable and non-tradable categories*

As section 2 highlights, splitting employment into jobs producing tradable versus non-tradable goods is a crucial part of our empirical strategy. This is not a trivial exercise. The difficulty is that many industries produce goods that fit into both non-tradable and tradable categories. For example, some banking services cater to local demand--a consumer may need a physical branch to deposit funds. Other banking services cater to national or international demand--for example, investment banking for large corporations. Given that many industries could be possibly categorized as producing both tradable and non-tradable goods, subjectivity is a real problem in this setting.

Our solution to this problem is two-fold. First, we use two independent classification schemes that follow objective criteria that disallow any subjective judgment. We describe these two methodologies below. Second, we carefully document these classification schemes and provide full disclosure on which industries fall into each category. Given the problem of subjectivity, our goal is to be as transparent as possible. As a side note, an advantage of our methodology outlined in Section 1 is that it is relatively immune to error in classification: As long as industries classified as “non-tradable” are legitimately non-tradable and the  $\alpha$  used in the calculations corresponds to this subset of industries, the overall methodology remains valid.

### 1. Retail and world trade based classification

For our first classification scheme, we define a 4-digit NAICS industry as *tradable* if it has imports plus exports equal to at least \$10,000 per worker, or if total exports plus imports for the NAICS 4-digit industry exceeds \$500M.<sup>13</sup> *Non-tradable* industries are defined as the retail sector and restaurants. We also use a more restricted version of non-tradable industries that includes only grocery retail stores and restaurants. A third category is *construction*, which we

---

<sup>13</sup> The industry level trade data for the U.S. is taken from Robert Feenstra’s website <http://cid.econ.ucdavis.edu>. The trade data is based on 2006 numbers.

define as industries related to construction, real estate, or land development. A large number of industries do not fit neatly into one of these three categories. We treat these other industries as a separate category we label as *other*. The shares of total employment as of 2007 for these four categories are: tradable (11%), non-tradable (20%), construction (11%), and other (59%).

Table 2 presents the top ten NAICS coded industries in each of our four categories based on the fraction of total employment as of 2007, and Appendix Table 1 lists all 294 4-digit industries and their classification. Industries producing tradable goods are mostly manufacturing, whereas non-tradable industries are concentrated in retail. The largest industries in the other category are service oriented industries such as health care, education, and finance.<sup>14</sup>

## 2. Geographical concentration based classification

An alternative is to classify industries as tradable and non-tradable based on an industry's geographical concentration. The idea is that the production of tradable goods requires specialization and scale, so industries producing tradable goods should be more concentrated geographically. Similarly, there are goods and services (such as vacation beaches and amusement parks) that may not be tradable themselves, but rely on national demand rather than local demand. For our empirical approach, these industries that are likely to be concentrated geographically should be classified as tradable. In contrast, industries producing non-tradable goods should be disperse given that all counties need such goods and services.

Our measure of geographical concentration of an industry is based on the employment share of the industry in each county. We use these shares to construct a geographical Herfindahl index for each industry. Consistent with the intuition that geographic concentration captures tradable and non-tradable goods production, we find a Herfindahl index of 0.018 for industries

---

<sup>14</sup> We exclude health care and education from our primary definition of non-tradables. However, our second method of classification based on geographical concentration allows these sectors to be classified as non-tradables.

that we classify as tradable in our first classification scheme, and a Herfindahl index of 0.004 for industries we classify as non-tradable. This is a large difference in Herfindahl given that the mean and standard deviation of Herfindahl index across industries is 0.016 and 0.023, respectively.

Table 3 lists the top 30 most concentrated industries and whether they are classified as tradable according to our previous categorization. There are a number of new industries classified as tradable according to the geographical concentration measure. The new classification is intuitive. For example, securities exchanges, sightseeing activities, amusement parks, and internet service providers all show up as tradable under the new scheme. This is sensible given that these activities cater to broader national level demand. Similarly, the bottom 30 industries include a number of industries that were not classified as non-tradable in our previous classification scheme. For example, lawn and garden stores, death care services, child care services, religious organizations, nursing care services are all industries that cater mostly to local demand but were missed in our previous classification scheme.

In short, geographical concentration based categorization of industries into tradable and non-tradable is intuitive and avoids subjectivity in selection. Our second classification scheme categorizes the top and bottom quartile of industries by geographical concentration as tradable and non-tradable, respectively.

### *C. Summary statistics*

Table 4 presents summary statistics for our sample. The average debt to income ratio of a county is 2.5 and there is a significant amount of variation. The standard deviation is 1.1 and the spread between the 10th and 90th percentile is large. Employment from 2007 to 2009 drops by an average of 5% across counties, which reflects the severity of the recession. Average wage

growth is positive from 2007 to 2009 at the mean, but negative at the 10th percentile. This wage data is from the county business pattern data set and wage is computed by dividing total payroll with the number of employees. As a result, it includes possible changes in the number of hours worked. There are significant differences in the declines in employment across the four categories of employment. The average decline in construction employment across counties is 12% during the recession. It is 12% for tradables, 2.5% for non-tradables, and 1.3% for the food industry.

The next set of variables in Table 4 comes from American Community Survey (ACS). They are based on survey responses and enable us to measure reported hourly wages directly. Since survey data is available at the individual response level, we can also construct various percentiles of the wage distribution for a given county. Average hourly wage as of 2007 is 17 dollars and average reported hourly wage growth is 4.8% from 2007 to 2009.

#### **Section 4: Deleveraging and Employment Losses**

In this section, we implement the methodology outlined in Section 2 to estimate the effect of the deleveraging driven-aggregate demand shock on aggregate employment.

##### *A. Deleveraging and employment losses in non-tradable and tradable Industries*

The left panel of Figure 3 presents the scatter-plot of employment losses in non-tradable industries (excluding construction) from 2007 to 2009 against the 2006 debt to income ratio of the county. There is a strong negative correlation. Even at the lowest end of the deleveraging shock, the predicted level of employment change is non-positive. As Proposition 1 explained, this is important for our aggregate calculation.<sup>15</sup> The thin black line in the left panel of Figure 3

---

<sup>15</sup> In our actual aggregate calculation, we are conservative and use the debt to income ratio at the 10th percentile of the distribution as our control group.

plots the non-parametric relationship between job losses in the non-tradable sector and county leverage. The non-parametric relationship closely follows the OLS predicted value; linearity is a reasonable assumption to explore the relationship between job losses and leverage.

While job losses in the non-tradable sector are strongly negatively correlated with the 2006 debt to income ratio of the county, the right panel of Figure 3 shows no such relation between leverage and job losses in the tradable sector. Instead, the OLS prediction has a negative constant and is flat across the entire distribution. As we discuss in Section 2, this is exactly the expected relation under the aggregate demand-deleveraging hypothesis given that the labor demand shock for tradable goods production should be evenly distributed across the economy.

Table 5 presents the regression coefficients relating employment growth in non-tradable industries from 2007 to 2009 to the 2006 debt to income ratio of the county. The instrumental variables estimate in column 3 implies that a one standard deviation increase in ex ante county leverage is associated with a 2.7% drop in employment in the non-tradable sector. Alternatively, moving from the 10th percentile of the leverage distribution to the 90th percentile is associated with a 6.2% larger drop in employment in industries producing non-tradable goods.

One concern is that counties with high debt to income ratio are somehow spuriously correlated with the type of industries they specialize in. If these industries received a stronger shock, then our results could be spurious. Column 4 includes as controls the share of employment devoted to each sector as of 2007 and the coefficient of interest is the same. We have experimented with introducing other industry controls at the county level – for example, the share of employment at the 2-digit industry level. Our main result remains unaffected.

Column 5 uses the alternative and stricter definition of non-tradables which includes only industries related to retail grocery and restaurants. This alternative definition is a strict subset of

our earlier definition. The coefficient on debt to income is negative and statistically significant, although it is slightly smaller than the column 2 estimate. The difference in magnitude most likely reflects the fact that demand for groceries is less elastic with respect to deleveraging shocks than other goods bought in retail stores.

Columns 6 and 7 report specifications relating job losses in the tradable sector to the 2006 debt to income ratio of a county. The coefficient is close to zero and precisely estimated. The difference between the coefficients for tradable job losses in column 6 and that for non-tradable job losses in column 1 is also statistically significant at the 1% level. The results in columns 6 and 7 also show a statistically significant negative coefficient on the constant. This reflects the fact that employment losses are evenly distributed across the entire country in industries producing tradable goods.

In order to quantify the tradable versus non-tradable results, it is useful to pick points in the 2006 debt to income distribution and calculate the marginal impact of the deleveraging shock going from low to high leverage counties. Consider a county at the 10th percentile of debt to income ratio (with a debt to income ratio of 1.5). Using the estimates from columns 4 and 7 of Table 5, the predicted drops in non-tradable and tradable employment from 2007 to 2009 are 0.3% and 11.6% respectively.<sup>16</sup> In contrast, the predicted employment drops in non-tradable and tradable sectors for the 90<sup>th</sup> percentile county with debt to income ratio of 3.8 are 5.1% and 11.6% respectively. The fact that high leverage counties experience a sharp employment drop in *both* tradable and non-tradable industries whereas low leverage counties experience an employment drop *only* in tradable industries is what allows us to identify the effect of deleveraging.

---

<sup>16</sup> Predicted values are estimated at the sample mean of construction, non-tradable and tradable employment shares in a county.

Figure 4 and Table 6 repeat the analysis using the geographical concentration based-definition of tradable and non-tradable industries. Despite being a completely different classification scheme, the results are remarkably similar. The left panel of Figure 4 and columns 1 through 4 of Table 6 show that the relationship between job losses in non-tradable industries – as defined by industries that are least concentrated geographically - and the debt to income ratio as of 2006 is strongly negative. The right panel of Figure 4 and the results in columns 5 and 6 of Table 6 show that the relationship between job losses in tradable industries – as defined by industries that are most concentrated geographically – and debt to income as of 2006 is completely uncorrelated.

### *B. Testing alternative explanations*

The decline in employment in industries producing non-tradable goods from 2007 to 2009 is concentrated in high leverage U.S. counties that simultaneously experience sharp relative declines in credit limits, house prices, debt levels, and consumption. The decline in employment in industries producing tradable goods is spread evenly across U.S. counties. These facts are strongly consistent with the deleveraging-aggregate demand hypothesis of high unemployment levels that we outline in Section 2 above. Could our results be explained by alternative hypotheses? We discuss this question below.

#### 1. The uncertainty hypothesis

A number of commentators and academics have put forth policy, regulatory, or business uncertainty as an explanation for the decline in macroeconomic aggregates (e.g. Bloom (2009), Bloom, Foetotto, and Jaimovich (2010), Fernandez-Villaverde, Guerron-Quintana, Kuester, and Rubio-Ramirez (2011), and Gilchrist, Sim, and Zakrajsek (2010)). As we show in Section 2, in its most basic form, an increase in business uncertainty at the *aggregate* level does not explain

the stark *cross-sectional* patterns in employment losses that we observe in non-tradable and tradable industries across U.S. counties. There may be more subtle versions of the uncertainty hypothesis that generate cross-sectional differences, but we have not seen them articulated.

## 2. The structural unemployment hypothesis

Another common explanation given for high unemployment is the displacement of workers from real estate related “bubble” industries such as construction and mortgages. Since job losses in these sectors are likely to be permanent once the bubble burst, it will take time for these workers to get re-trained and absorbed in alternative industries. We refer to this as the structural unemployment hypothesis.

There are a number of reasons already shown why the structural unemployment hypothesis is unlikely to explain our results. In the above results, we explicitly remove any employment associated with the construction, real estate, or mortgages from our non-tradable definition. Given this exclusion, the strong correlation between leverage and the decline in non-tradable employment decline is unlikely to be driven by construction related shocks.

However, perhaps our debt to income measure as of 2006 is correlated with the construction sector shock, and a negative shock to construction indirectly affects other non-tradable sector employment. Table 7 tests this concern by first correlating the 2006 debt to income ratio across counties with the county-level share of employment in construction in 2007, and the growth in construction related employment from 2000 to 2007. Columns 1 and 3 of Table 7 show that both these measures of exposure to the construction sector in a county are positively correlated with the 2006 debt to income ratio. How can we be sure that we are capturing a deleveraging effect and not a construction effect?

One answer is in results shown above. In Tables 5 and 6, we include the share of workers in construction as of 2007 as a control variable. The inclusion of this control does not affect the results. In fact, the construction share of employment as of 2007 is barely correlated with job losses in non-construction non-tradable industries when no other variables are included.<sup>17</sup>

A second answer lies in our instrumental variables specification. Columns 2 and 4 of Table 7 show that when we instrument the 2006 debt to income ratio using housing supply elasticity, the predicted values of the debt to income ratio are *not* correlated with either the construction share as of 2007 or the growth in the construction share from 2000 to 2007. In other words, when we isolate the variation in the 2006 debt to income ratio that comes from housing supply elasticity, the variation is uncorrelated with the construction sector.

Recall that column 4 in Table 1 shows that the debt to income ratio as of 2006 is strongly correlated with housing supply elasticity, with an  $R^2$  over 19%. Why is the instrumented debt to income ratio uncorrelated with the construction share and the growth in construction sector in Table 7? The answer lies in the dual role played by the elasticity instrument. On one hand, less elastic counties saw sharper increases in house prices during the boom. The increase in house prices made credit more easily available due to higher collateral value therefore facilitating more construction activity. On the other hand, less elastic counties have – by definition – a higher marginal cost to expand the housing stock. The combination of these two opposing forces makes housing elasticity uncorrelated with construction activity, but strongly correlated with the accumulation of leverage due to the home equity borrowing effect.

---

<sup>17</sup> See the middle panel of Appendix Figure 1. When we estimate the corresponding weighted least squares regression in column 1 of Table 5 using the construction share of employment as of 2007 instead of the debt to income ratio as of 2006, the coefficient is -0.047 with a p-value of 0.123. The standard deviation of the construction share is only 0.057. This implies both a very small and statistically weak effect of the construction share on subsequent employment losses in non-construction non-tradable industries. In contrast, the debt to income ratio as of 2006 does an excellent job predicting job losses in the construction sector. See the right panel of Appendix Figure 1.

### 3. The credit supply hypothesis

Another possible explanation for high unemployment is based on counties experiencing differential credit supply shocks depending on the severity of the house price collapse. Because leverage as of 2006 is strongly correlated with subsequent house price declines and real estate may be used as collateral for business credit, collateral-induced tightness in business credit might reduce employment in high leverage counties.

One problem with this alternative explanation is that it does not explain why job losses in high leverage counties were concentrated in non-tradable industries. An explanation based on credit supply would imply more job losses within high leverage counties in *all* industries--we find no such effect in industries producing tradable goods.

But a counter-argument is that the non-tradable sector may be more susceptible to credit supply shocks. To address this issue, we take advantage of the CBP data which records employment separately for establishments by various size categories. Table 8 shows that the negative correlation between employment growth in non-tradable industries from 2007 to 2009 and the ex ante county leverage ratio is stronger in *large* establishments. Under the assumption that smaller firms face tighter financial constraints, the results dispute a credit supply based explanation.

#### *C. Other labor market margins of adjustment: Wages and labor mobility*

Figures 2, 3 and 4 show a very large decline in employment in high leverage counties relative to low leverage counties. As discussed in Section 2.D, we now consider how the large decline in employment in these areas affects wages and labor mobility.

We begin with wages. In the absence of absolute wage rigidity, we should expect at least some downward response of wages to the large decline in employment in high leverage counties.

In Table 9 and the left panel of Figure 5, we find evidence of this effect. In both the left panel of Figure 5 and in columns 1 through 4 of Table 9, we use county level data on wages from the Census County Business Patterns. We find that debt to income ratios as of 2006 have a negative effect on total wage growth from 2007 to 2009. The coefficient in column 2 implies that a one standard deviation increase in the 2006 debt to income ratio leads to 1% lower wage growth, which is about 1/5 a standard deviation. The instrumental variables estimate in column 4 is twice as large.

The advantage of Census data is that it is based on actual IRS payroll data for current employees and is therefore very accurate. The disadvantage is that it only tracks the wages per employee and does not record the hours worked by an employee. As a result, the decline in wages we find in Table 9 may be due to a decline in the number of hours worked by a given employee, not by a lower wage to the employee.

In columns 5 through 7, we use survey data from the American Community Survey on hourly wages. The advantage of the ACS data is that it tracks hourly wages, not total wages per employee. The disadvantage is that the ACS is based on survey data that is likely to be less accurate than payroll data. Regardless, column 5 shows a similar negative effect of county leverage as of 2006 on hourly wage growth. The similarity of the CBP and ACS results are reassuring that the CBP result is not being driven by workers cutting the number of work-hours.

The ACS also allows us to split the wage effect across the distribution of wages. The right panel of Figure 5 shows a negative relation between wages at the 25th percentile of the distribution and the 2006 debt to income ratio of a county. Columns 6 and 7 examine the correlation between debt to income and wage growth at the 10th and 90th percentile of the wage

distribution. We find suggestive evidence that wages decline by more in the lower part of the wage distribution.

Another margin on which workers may adjust is mobility. Facing extremely high unemployment rates, workers in high leverage counties may choose to move out of the area. In the left panel of Figure 6, we utilize state level data on population from the Census.<sup>18</sup> From 2007 to 2009, population growth is in fact *positively* correlated with the 2006 debt to income ratio at the state level. In other words, despite the collapsing economy in high debt to income states, the population is growing faster in these states.

Column 1 of Table 10 confirms this positive correlation and shows that it is statistically significant at the 5% level. The specification in column 2 utilizes net migration in 2008 and 2009 as a fraction of population in 2007. Net migration helps eliminate the effect of population growth driven by fertility differences. The point estimate remains positive but is not significantly different than zero. Columns 1 and 2 of Table 10 help ensure that the employment declines in high leverage areas are not due to people moving out of the area.

An alternative check to ensure that our results are not driven by a decline in available labor force in high leverage counties is to directly look at labor force growth between 2007 and 2009 at the county level. This information is provided by the BLS. The right panel of Figure 6 plots labor force growth from 2007 to 2009 in counties against the debt to income ratio as of 2006. There is a slightly positive relation but it is extremely noisy. Columns 3 and 4 of Table 10 show coefficients consistent with the scatter-plot in Figure 6: the correlation is positive but statistically unreliable. The IV version of this regression is positive in column 4. In other words, there is no evidence that high leverage counties experienced disproportionate losses in

---

<sup>18</sup> We do not have county-level measures of population through 2009.

population or labor force participation. If anything, there is some evidence that high leverage areas continued to grow more strongly in terms of the labor force from 2007 to 2009.

## Section 5: The Aggregate Calculation

### A. Baseline calculation

We can now apply the methodology outlined in section 1 and summarized by Proposition 1 to compute the aggregate loss in employment due to deleveraging. The employment loss due to deleveraging is given by  $\frac{1}{\alpha} [\sum_{c=2}^N \widehat{\Delta Y_c^{NT}}]$ , where  $\widehat{\Delta Y_c^{NT}} = [E(Y_c^{NT} | X_c) - E(Y_1^{NT} | X_1)]$ .

The relationship between non-tradable employment loss and 2006 leverage is almost linear (see Figure 3). We can therefore use results from our main linear regression specification (column 1 of Table 5) to estimate  $\widehat{\Delta Y_c^{NT}}$  for each county. This is done by using the predicted value for each county from column 1 of Table 5, and subtracting the predicted value of employment losses for the county with the lowest leverage in 2006.

In order to be conservative and also to avoid basing our estimate on potentially noisy outliers in our sample distribution, we pick the 10<sup>th</sup> percentile of leverage distribution as our base county. Therefore,  $E(Y_1^{NT} | X_1)$  equals the predicted non-tradable employment losses for the county that corresponds to the 10<sup>th</sup> percentile of cross-county 2006 leverage distribution.  $\widehat{\Delta Y_c^{NT}}$  is set to zero for all counties below the 10<sup>th</sup> percentile county.

While this is also visually apparent from Figure 3, the predicted log change in non-tradable employment for the 10<sup>th</sup> percentile county is negative and equals -0.0057. As stated in Proposition 1, it is important for our calculation that our base county non-tradable employment change be negative.

We multiply the predicted percentage change in non-tradable employment for a given county by the level of non-tradable employment in 2007 in that county to compute the predicted change in number of non-tradable jobs. Summing this estimate across counties gives us an estimate of 777 thousand jobs lost in the *non-tradable* sector due to the deleveraging shock.

In order to translate this number into total jobs lost across all sectors, we need to multiply it by the inverse of the share of non-tradable sector,  $1/\alpha$ . Given a share of 19.6% of non-tradable employment in total employment, we get an estimate of 3.96 million jobs lost across all sectors due to the deleveraging shock. The total number of jobs lost in our data between 2007 and 2009 equals 6.05 million jobs. As a result, our estimated jobs lost due to the deleveraging shock equals 65.4% of total jobs lost in the economy from 2007 to 2009.

#### *B. Robustness to alternative assumptions*

Our estimate for jobs lost due to deleveraging is likely to be an underestimate of the true effect for two reasons. First, as is highlighted in Proposition 1, we do not include in our estimate jobs lost due to deleveraging in the lowest end of county distribution. In fact we have been cautious in using only the 10<sup>th</sup> percentile as our base county. If we were to use the 5<sup>th</sup> percentile county instead, which has predicted log change employment of -0.0017, then our estimated job loss due to deleveraging would have been 4.45 million jobs or 73.4% of total jobs lost.

Second, our methodology in Section 1 assumes that in response to a deleveraging shock, consumers cut back on tradable and non-tradable goods proportionately. There is a legitimate reason to believe that demand for industries not included in the non-tradable definition such as durable goods and construction are *more* sensitive to a deleveraging shock. Incorporating a higher income elasticity of demand for industries not included in the non-tradable sector would increase our estimate of jobs lost. Based on these factors, we feel that our reported estimate -

while already large and significant - is likely to be an underestimate of the true employment losses due to deleveraging.

Our macro calculation could have been an overestimate of the true job losses in the economy due to the deleveraging shock if relative wage declines in high leverage counties had attracted more jobs in the tradable sector. However, we see no evidence of that as the relationship between employment declines in the tradable sector and county leverage is zero and precisely estimated.<sup>19</sup>

## **Section 6: Conclusion**

Household debt in the United States reached unprecedented levels before the onset of the recession. The extant literature strongly supports the view that the onset of the recession was driven by a series of shocks that required deleveraging of the household sector. In counties with high levels of leverage as of 2006, house prices declined by 30% from 2007 to 2010. Home equity limits and total debt also experienced severe declines in these areas. Mian, Rao, and Sufi (2011) show that the drop in consumption of all types of goods from 2007 to 2010 was much more severe in high leverage counties.

In this study, we estimate how the deleveraging process affected employment levels during the heart of the recession. Our main insight is that the relation between deleveraging and employment losses in industries catering to local demand can be used to estimate the effect of deleveraging on aggregate unemployment. We estimate that 4 million of the 6.2 million jobs lost between March 2007 and March 2009 were due to deleveraging of the household sector. Based

---

<sup>19</sup> There remains a possible external adjustment mechanism via trade with the rest of the world. In particular, a serious devaluation of the dollar may induce job creation in the overall export sector all across the U.S. However, job gains in the export sector remain modest, and as the summary statistics in Table 3 show, between 2007 and 2009, job losses in the tradable sector were 4.9% and higher than losses in any other sector. The export-adjustment margin is unlikely to be very meaningful for job creation during the 2007 to 2009 period.

on this analysis, we believe that high levels of household debt and the deleveraging process are the main reasons for historically high unemployment in the U.S. economy.

Alternative hypotheses such as business uncertainty and structural adjustment of the labor force related to construction are less consistent with the facts. The argument that businesses are holding back hiring because of regulatory or financial uncertainty is difficult to reconcile with the strong cross-sectional relation between household leverage levels, consumption, and employment in the non-tradable sector. This argument is also difficult to reconcile with survey evidence from small businesses and economists saying that lack of product demand has been the primary worry for businesses throughout the recession (Dennis (2010), Izzo (2011)).

There is certainly validity to the structural adjustment argument given large employment losses associated with the construction sector. However, we show that the leverage ratio of a county is a far more powerful predictor of total employment losses than either the growth in construction employment during the housing boom or the construction share of the labor force as of 2007. Further, using variation across the country in housing supply elasticity, we show that the deleveraging hypothesis is distinct from the construction collapse view. Finally, structural adjustment theories based on construction do not explain why employment has declined sharply in industries producing tradable goods even in areas that experienced no housing boom.

**Figure 1**  
**Deleveraging and Consumption**

This figure plots house prices, home equity limits, household borrowing, and auto sales for high and low household leverage counties in the U.S. from 2006 to 2010. High and low household leverage counties are defined to be the top and bottom quartile counties based on the debt to income ratio as of 2006. Quartiles are weighted by the outcome variable in question as of 2006 so that both quartiles contain the same amount of the outcome variable as of 2006 (for house prices we weight by population).

**Figure 2**  
**Deleveraging and Employment across Counties: All Industries**

This figure presents a scatter-plot of county level employment growth from 2007Q1 to 2009Q1 against the debt to income ratio of the county as of 2006. All industries are included. The sample includes only counties with more than 50,000 households.

**Figure 3**

**Deleveraging and Employment across Counties: Non-Tradable and Tradable Industries**

This figure presents scatter-plots of county level employment growth from 2007Q1 to 2009Q1 against the debt to income ratio of the county as of 2006. The left panel examines employment in non-tradable industries excluding construction and the right panel focuses on tradable industries. The sample includes only counties with more than 50,000 households. The thin black line in left panel is the non-parametric plot of non-tradable employment growth against debt to income.

**Figure 4**

**Deleveraging and Employment across Counties: Geographical Herfindahl-Based Non-Tradable and Tradable Industries**

This figure presents scatter-plots of county level employment growth from 2007Q1 to 2009Q1 against the debt to income ratio of the county as of 2006. The left panel examines employment in non-tradable industries based on geographical herfindahl index and the right panel focuses on tradable industries based on the same index. The sample includes only counties with more than 50,000 households.

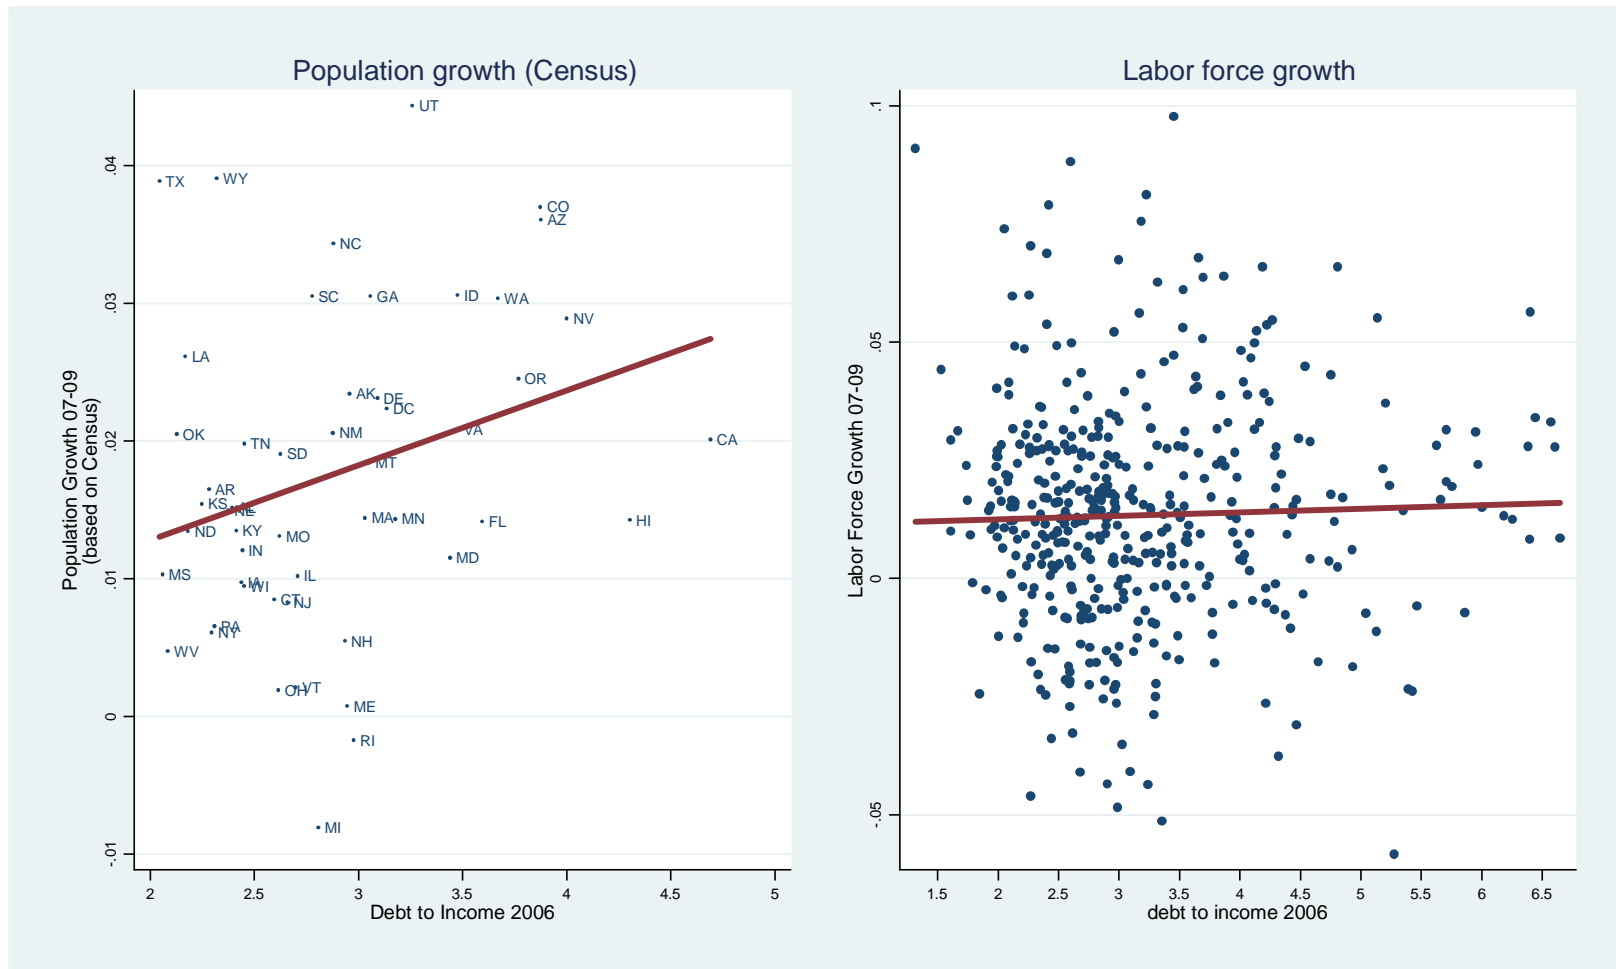

**Figure 5**  
**Deleveraging and Wage Growth across Counties**

This figure presents scatter-plots of hourly wage growth from 2007Q1 to 2009Q1 against the debt to income ratio of the county as of 2006. The left panel examines all wages and the right panel examines wages at the 25th percentile of the distribution. The sample includes only counties with more than 50,000 households.

**Figure 6**  
**Deleveraging and Mobility**

This figure presents scatter-plots of mobility from 2007 to 2009 against the debt to income ratio of the county/state as of 2006. The left panel utilizes state level data from the Census on total population growth. The right panel uses labor force data from the county business patterns. The sample for the right panel includes only counties with more than 50,000 households.

**Table 1**  
**Deleveraging and Employment**

This table presents regression coefficients relating employment growth in a county from 2007 to 2009 to the debt to income ratio of the county in 2006. The specification "WLS" is weighted least squares where the weights are total number of households in the county. The instrumental variables specifications in column 5 uses the housing supply elasticity of the county (Saiz (2011)) as an instrument for the debt to income ratio in the first stage, which is reported in column 4. Standard errors are heteroskedasticity robust.

	(1)	(2)	(3)	(4)	(5)
		Employment growth, 2007-2009		Debt to income, 2006	Employment growth, 2007-2009

\*\*,\* Coefficient statistically different than zero at the 1% and 5% confidence level, respectively

**Table 2**  
**Industry Categorization**

This table presents the largest 10 industries in each category of goods produced. The % column gives the percentage of the entire 2007 labor force represented by the industry in question. Please see the text for the methodology used to categorize each industry. See Appendix Table 1 for a complete list of industries and their category.

<b>Non-tradable Industries</b> (19.6% of total employment)			<b>Tradable Industries</b> (10.7% of total employment)		
		%	NAICS	Industry name	%
7221	Full-service restaurants	3.76	3261	Plastics product manufacturing	0.60
7222	Limited-service eating places	3.40	3231	Printing and related support activities	0.53
4451	Grocery stores	2.13	3363	Motor vehicle parts manufacturing	0.52
4521	Department stores	1.36	3116	Animal slaughtering and processing	0.44
4529	Other general merchandise stores	1.12	3364	Aerospace product and parts manufacturing	0.35
4481	Clothing stores	1.06	3327	Machine shops; screw nut and bolt manufacturing	0.33
4461	Health and personal care stores	0.89	3345	Navigational and control instruments manufacturing	0.33
4471	Gasoline stations	0.73	3344	Semiconductor and other electronic manufacturing	0.32
7223	Special food services	0.49	3399	Other miscellaneous manufacturing	0.31
4511	Sporting goods hobby and music stores	0.38	5112	Software publishers	0.29
<b>Construction Industries</b> (11.2% of total employment)			<b>Other Industries</b> (58.5% of total employment)		
NAICS	Industry name	%	NAICS	Industry name	%
2382	Building equipment contractors	1.62	6221	General medical and surgical hospitals	4.31
5413	Architectural engineering and related services	1.19	5511	Management of companies and enterprises	2.60
4441	Building material and supplies dealers	1.00	5613	Employment services	2.56
2381	Foundation structure and building contractors	0.91	6211	Offices of physicians	1.79
2383	Building finishing contractors	0.78	5221	Depository credit intermediation	1.77
2361	Residential building construction	0.75	7211	Traveler accommodation	1.54
2362	Nonresidential building construction	0.64	5617	Services to buildings and dwellings	1.42
5313	Activities related to real estate	0.54	8131	Religious organizations	1.39
2389	Other specialty trade contractors	0.48	6231	Nursing care facilities	1.37
5311	Lessors of real estate	0.45	6113	Colleges universities and professional schools	1.35

**Table 3****Industry Categorization Based On Geographical Concentration**

This table lists the top and bottom 30 industries by geographical concentration. For each industry we compute Herfindahl index based on the shares of employment for that industry across counties. The most concentrated (top 30) are likely to be “tradable” in that they depend on national or international demand. If an industry needs to be physically present in an area to provide its goods or services, then it is likely to be non-tradable and least concentrated (bottom 30). The indicator variable for traded and non-traded reports the classification according to our other methodology reported in Table 2.

<b>Herfindahl Top-30</b>		<b>Herfindahl Bottom-30</b>	
Industry name	Traded?	Industry name	Non-Traded?
Securities and commodity exchanges	0	Lawn and garden equipment stores	0
Pipeline transportation of crude oil	0	Farm product raw material wholesalers	0
Cut and sew apparel manufacturing	1	Gasoline stations	1
Motion picture and video industries	0	Nonmetallic mineral mining and quarrying	0
Agents and managers for artists athletes	0	Other general merchandise stores	1
Deep sea coastal and lakes transportation	0	RV parks and recreational camps	0
Cable and other subscription programming	0	Sawmills and wood preservation	0
Sound recording industries	0	Florists	1
Tobacco manufacturing	1	Death care services	0
Independent artists writers and performers	0	General rental centers	0
Railroad rolling stock manufacturing	1	Direct selling establishments	0
Scenic and sightseeing transportation other	0	Building material and supplies dealers	0
Amusement parks and arcades	0	Other motor vehicle dealers	1
Scenic and sightseeing transportation water	0	Nursing care facilities	0
Securities and commodity brokerage	0	Automotive parts accessories and tire stores	1
Internet Service Providers and Web Search	0	Logging	0
Metal ore mining	1	Specialized freight trucking	0
Support activities for water transportation	0	Cement and concrete product manufacturing	0
Apparel goods wholesalers	0	Other wood product manufacturing	0
Other support activities for transportation	0	mental health and substance abuse facilities	0
Monetary authorities- central bank	0	Beer wine and liquor stores	1
Oil and gas extraction	1	Community care facilities for the elderly	0
Fishing	1	Child day care services	0
Apparel knitting mills	1	Vocational rehabilitation services	0
Internet Publishing and Broadcasting	0	Consumer goods rental	0
Pipeline transportation of natural gas	0	Electric power generation transmission	0
Footwear manufacturing	1	Plastics product manufacturing	0
Manufacturing magnetic and optical media	1	Religious organizations	0
Ship and boat building	1	Animal food manufacturing	0
Textile furnishings mills	1	Highway street and bridge construction	0

**Table 4**  
**Summary Statistics**

This table presents summary statistics for the county-level data used in the analysis. Employment data are from the Census County Business Patterns, wage data are from the American Community Survey, debt data are from Equifax, and income data are from the IRS. The last two columns are weighted by the number of households in the county as of 2000.

	N	Mean	SD	10 <sup>th</sup>	90 <sup>th</sup>	Weighted mean	Weighted SD
Debt to income, 2006	3136	2.526	1.080	1.466	3.798	3.117	1.074
Number of households, 2000, thousands	3137	37	111	2	73	370	620
Labor force growth, 2007 to 2009	3137	0.012	0.041	-0.035	0.055	0.013	0.029
Total employment, 2007, thousands	3137	39	138	1	74	439	754
Employment growth, 2007 to 2009	3137	-0.048	0.103	-0.157	0.057	-0.052	0.056

Wage growth, median, 2007 to 2009	3141	0.056	0.080	-0.044	0.163	0.044	0.056
Wage growth, 75th percentile, 2007 to 2009	3141	0.079	0.061	0.011	0.158	0.060	0.047
Wage growth, 90th percentile, 2007 to 2009	3141	0.048	0.067	-0.033	0.139	0.035	0.046

**Table 5**  
**Deleveraging and Unemployment across Counties: Non-Tradable And Tradable Industries**

This table presents coefficients from regressions relating employment growth in a county from 2007 to 2009 to the debt to income ratio of the county as of 2006. We split employment into non-tradable and tradable industries. The specification "WLS" is weighted least squares where the weights are total number of households in the county. The instrumental variables specification in column 3 uses the housing supply elasticity of the county (Saiz (2011)) as an instrument for the debt to income ratio in the first stage. Standard errors are heteroskedasticity robust.

	(1)	(2)	(3)	(4)	(5)	(6)	(7)

\*\*,\* Coefficient statistically different than zero at the 1% and 5% confidence level, respectively

**Table 6**  
**Deleveraging and Employment Growth in Non-Tradable Industries**  
**Using Concentration to Measure Tradability**

This table presents coefficients from regressions relating employment growth in a county from 2007 to 2009 to the debt to income ratio of the county as of 2006. We use an alternative measure of non-tradable industries based on the concentration of employment across counties--low concentration industries are assumed to be more non-tradable. Columns 1 through 4 examine industries in the bottom quartile based on concentration, columns 5 and 6 use a continuous measure of concentration, and columns 7 and 8 examine industries in the top quartile based on concentration. Standard errors are heteroskedasticity robust.

Dependent variable	(1)	(2)	(3)	(4)	(5)	(6)
Industries?	Lowest concentration quartile industries			Highest concentration quartile industries		
	Employment growth, 2007-2009					
Debt to income, 2006	-0.016** (0.002)	-0.019** (0.002)	-0.024** (0.006)	-0.016** (0.002)	0.010 (0.006)	0.003 (0.007)
Lowest Concentration Quartile Share, 2007				-0.000 (0.000)

**Table 9**  
**Deleveraging and Wage Growth across Counties**

This table presents coefficients from regressions relating wage growth in a county from 2007 to 2009 to the debt to income ratio of the county as of 2006. The specifications in columns 1 through 4 use total wages from the Census County Business Patterns data. The specifications in columns 5 through 7 use hourly wage growth data from the American Community Survey. "WLS" is weighted least squares where the weights are total number of households in the county. The instrumental variables specification in column 4 uses the housing supply elasticity of the county (Saiz (2011)) as an instrument for the debt to income ratio in the first stage. Standard errors are heteroskedasticity robust.

Dependent variable	(1)	(2)	(3)	(4)	(5)	(6)	(7)

**Table 10**  
**Deleveraging, Mobility, and Labor Supply across Counties**

This table presents coefficients from regressions relating mobility and labor force participation in a county from 2007 to 2009 to the debt to income ratio of the county as of 2006. The specifications in columns 1 through 2 use state level data on population and net migration from the American Community Survey. The specifications in columns 3 through 6 use labor force data from the Census County Business Patterns. "WLS" is weighted least squares where the weights are total number of households in the county. The instrumental variables specification in column 5 uses the housing supply elasticity of the county (Saiz (2011)) as an instrument for the debt to income ratio in the first stage. Standard errors are heteroskedasticity robust.

Dependent variable	(1) Population growth, 2007-2009	(2) Net migration, 2007-2009	(3)	(4) Labor force growth, 2007-2009	(5)

## Appendix Figure 1 Deleveraging and Construction

The left panel replicates the left panel of Figure 3 from the analysis. The middle panel plots the employment losses from 2007 to 2009 in industries producing non-tradable goods against the share of workers in the construction industry as of 2007. The right panel plots employment losses in the construction industry against the debt to income ratio as of 2006.
